Practical 3: Databases Searching

Wednesday 6 July 2016

Searching for sequence similarities in databases.

The most popular way to investigate a sequence has always been to compare it with one of the sequence databases now accessible from sites all over the world. When sequences databases were more sparsely populated than now, the objective was to search hopefully, not always with success, for any convincingly similar sequence(s). When such a match was discovered, it could be supposed that known properties of the "similar" database sequence might provide insight to the properties of the query sequence. Now, the databases are full of sequences representative of most interesting conditions. Similarity searches are conducted in the expectation of finding many close "hits" for almost any sequence. Fewer database searches are conducted in complete ignorance of what the query sequence might be.

Here, take the **PAX6** genomic DNA sequence retrieved from **Ensembl** and conduct two searches analogous to those run in the **Ensembl** pipeline. Results should confirm that which has already been discovered using other sources.

blast is not the only sequence database searching program available, but it is the most popular by a very long way. **blast** searches are offered in many forms by many servers all over the world, but the most comprehensive and reliable service has to be that offered by the **NCBI**.

Go to the NCBI homepage at:

http://ncbi.nlm.nih.gov

Select the **BLAST** option (from the **Popular Resources** list). In the **Basic BLAST** section, select **nucleotide blast**.

Use the Enter Query Sequence
Browse (or Choose File) button
to upload the file:

| blastn | blastx | tblastn | tblastx | tblastn | tblas

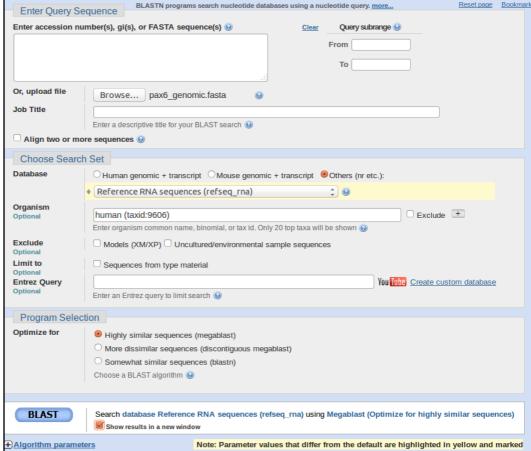

pax6_genomic.fasta.

For results like those used by **Ensembl** to predict **PAX6** transcripts, you must compare your genomic sequence to a reliable set of human mRNA/cDNA (or similar) sequences.

In the Choose Search Set section, set the Database to Reference RNA sequences (refeseq rna).

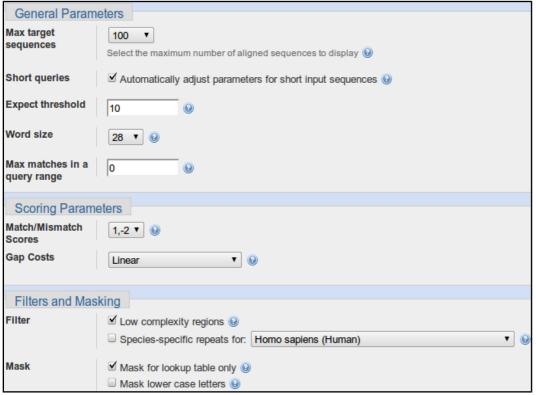

You are now able to specify an **Organism**, choose **Human**.

blast is now set to compare the **PAX6** genomic region with all **Human** mRNA sequences in **RefSeq**.

Note that the default **Program Selection** is **Highly similar sequences (megablast**¹), which seems appropriate here as all the mRNA that correctly match should surely do so almost perfectly.

Click on the Algorithm Parameters button. The defaults are fine here, but before starting your search, try changing the Program Selection and observing the different Algorithm Parameters.

The default settings of all shared parameters are identical for the two slower more sensitive **Program Selections**.

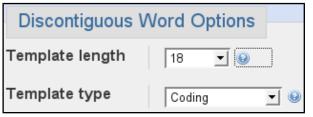

There are differences for **megablast**, where speed is of the essence and sensitivity can be sacrificed.

Smaller Word sizes slow searches but increase sensitivity. For megablast the default Word size is 28 otherwise it is 11.

Gapped alignment is time consuming and, by default, considered more crudely by **megablast** than the other two algorithms².

Filtering and Masking matches with organism specific repeats and/or low complexity regions takes time, and so only avoiding Low complexity regions³ is on by default for all **Program Selections**.

When **discontinuous megablast** is selected, an extra options section appears. Discussing how this flavour of **blast** works is a little beyond the scope of these note, but briefly. Unlike the other **Program Selections**, **discontinuous megablast** does not just look for exactly matching "words" of given size as a first step towards identifying matching regions between sequences. It looks for a pattern of matching bases within a word. For example, the default

choice assumes your query is **coding** and looks for **11** matching bases within a word of **18**. Approximately, every third base is allowed not to match. Biologically, this can be justified as allowing for third codon position wobble. For more detail, use the appropriate button. Notice there are buttons by every parameter selection. Try one or two. In the process, discover:

When would **Mask lower case letters** be a useful thing to do?

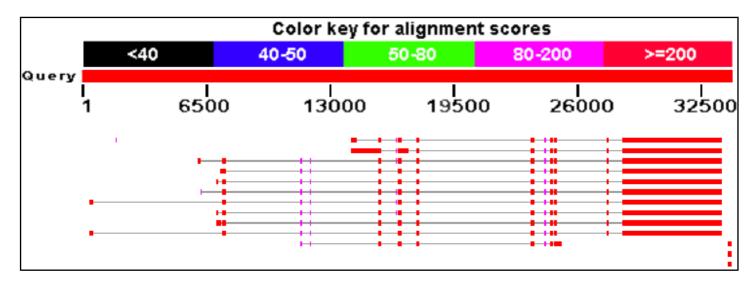

Automatically adjust parameters for short input sequences is independent of Program selection, and so remains unaltered.

Which parameters would **blast** need to **automatically adjust** to cater for short input sequences (such as primers being tested for uniqueness), and why?

² By default, megablast uses Linear Gap Costs. That is, it just multiplies the size of the gap with the Mismatch penalty. The other two algorithms employ the more common Affine strategy, using Existence and Extension penalties. For more about Gap Penalties, go here.

This filter avoids finding "hits" supported only by matches in regions not specific to the query. For example, a polyA tail cannot help to identify a specific mRNA as it is present is all mRNAs. The use of this filter will be evident when we look at the **blast** output.

Finally, ensure all the defaults are back in place and the **megablast** is the **Program Selection**, ask **blast** to **Show results in a new window** and then click on the **blast** button. Impressively swiftly, you will have results. At the top of which will be a graphical overview.

This graphic implies that there are 11 full length matches between the genomic sequence and mRNAs in **RefSeq**. The **RefSeq** entries had to be "gapped" in order to compensate for the introns that are represented in the genomic sequence but not in the mRNA sequences. The **red blocks** therefore represent very closely matching (>=200 brownie points) exons, the lines joining the **red blocks** represent introns that have been spliced out. All 11 full length hits match reasonably uniformly except for the first few exons, implying significant variation in the 5′ UTR.

why do you suppose that a fev	of the exons of the first 1.	I matches do not achieve the r	naximum score!

Explain why one exon in the reasonably consistent region, does not appear in all of the transcript matches?

In a previous Practical, you discovered directly that there were 11 high quality "NM" PAX6 transcripts in RefSeq.

Until recently, there was a further **9** "**XM**_" **PREDICTED** transcripts. However, in the last release of **RefSeq**, the **9** less reliable **XM**_ transcripts were removed. Nevertheless, you saw that the **9 PREDICTED** transcripts are still evidenced in **MapViewer**. That is because the current version of **MapViewer** is built on a previous version of **RefSeq**. As soon as **MapViewer** is updated, the dubious **9** will disappear. Then, I will have to discover another way to introduce the way that **RefSeq** divides its transcript entries by quality.

Ensembl claimed to have used 10 or the 11 high quality NM_ RefSeq sequences to aid its transcript predictions. Ensembl would have ignored the XM_ PREDICTED RefSeq sequences even if they still existed.

blast just sees sequences and cannot be influenced by the quality of the support for their existence, so **blast** will always report all **RefSeq PAX6** mRNAs matching the **PAX6** genomic region convincingly, however questionably they are evidenced.

There is a point to pursuing all this detail. You reference a collection of interdependent databases, all of which are updated regularly. More often than not you will notice inconsistencies due to asynchronous updates and differences in database management policy. A small price to pay for such a rich source of information, but one of which I suggest it is wise to be aware.

The message of the particular **blast** search here is that it is so easy to predict the same **PAX6** transcripts as you discovered in **MapViewer**, just with a simple **blast** search. That is, you can look things up, or work most of it out for yourself.

If you have any non-default settings, they should be highlighted in yellow.

If you hover over the graphical hits, their origin will be displayed above the graphic⁵.

Below the **Graphic Summary** are the **Descriptions**, a simple list of the **15** matches represented in the graphic.

Description	Max score	Total score	Query cover	E value	Ident	Accession
Homo sapiens paired box 6 (PAX6), transcript variant 11, mRNA	9659	12484	19%	0.0	99%	NM 001310161.1
Homo sapiens paired box 6 (PAX6), transcript variant 10, mRNA	9659	15161	24%	0.0	99%	NM 001310160.1
Homo sapiens paired box 6 (PAX6), transcript variant 8, mRNA	9659	12929	20%	0.0	99%	NM 001310158.1
Homo sapiens paired box 6 (PAX6), transcript variant 7, mRNA	9659	12729	20%	0.0	99%	NM 001258465.1
Homo sapiens paired box 6 (PAX6), transcript variant 6, mRNA	9659	12761	20%	0.0	99%	NM 001258464.1
Homo sapiens paired box 6 (PAX6), transcript variant 5, mRNA	9659	12737	20%	0.0	99%	NM 001258463.1
Homo sapiens paired box 6 (PAX6), transcript variant 4, mRNA	9659	12862	20%	0.0	99%	NM 001258462.1
Homo sapiens paired box 6 (PAX6), transcript variant 2, mRNA	9659	12833	20%	0.0	99%	NM 001604.5
Homo sapiens paired box 6 (PAX6), transcript variant 1, mRNA	9659	12942	20%	0.0	99%	NM 000280.4
Homo sapiens paired box 6 (PAX6), transcript variant 3, mRNA	9659	12791	20%	0.0	99%	NM 001127612.1
Homo sapiens paired box 6 (PAX6), transcript variant 9, mRNA	647	2630	4%	0.0	100%	NM 001310159.1
Homo sapiens elongator acetyltransferase complex subunit 4 (ELP4), transcript variant 3,	433	433	0%	8e-118	100%	NM 001288726.1
Homo sapiens elongator acetyltransferase complex subunit 4 (ELP4), transcript variant 2,	433	433	0%	8e-118	100%	NM 001288725.1
Homo sapiens elongator acetyltransferase complex subunit 4 (ELP4), transcript variant 1,	433	433	0%	8e-118	100%	NM 019040.4
Homo sapiens uncharacterized LOC440034 (DKFZp686K1684), long non-coding RNA	141	141	0%	5e-30	100%	NR 033971.1

These are such that:

- The top 11 hits, corresponding to the 11 full length hits of the **Graphic Summary**, are the quality (i.e. **NM**_ entries with good supporting evidence) **RefSeq** transcripts.
- There follows, corresponding to the 3 small red blobs in the extreme bottom right of the **Graphic Summary**, 3 hits that are the ends of mRNAs for the ELP4 gene. They are exactly where you should expect them to be, assuming you paid full attention to the ELP4 transcript predictions shown in both the **Ensembl** and **MapView** displays of the **Genomic** region around **PAX6**. Reject these contemptuously, they do not pertain to our investigation of **PAX6**.
- The 15th match, corresponding to the barely visible tiny smudge match to the left of the top **Graphic Summary** hit, is recorded as "uncharacterized" and fails to fit in with my story, so I ignore it!

So, this **blast** search suggests the existence of **11 PAX6** transcripts supported by **RefSeq** data, as will be reported by **MapView** as soon as the **NCBI** get around to bringing it up to date! Also, the results are consistent with the information discovered in **Ensembl**.

Which of the **Refseq PAX6** transcripts corresponds to **isoform 5a?**

⁵ Or you could just read the textual list that follows the graphic if you wish to insist on the simplistic.

Moving further down the results you will come to the alignments between the **PAX6** genomic sequence and the matching database entries. All similarity searches use local alignment strategies⁶, so you should not be surprised to see a number of alignments for each "hit" in the list. Here we have a genomic query sequence aligned exclusively with mRNA sequences from **RefSeq**. The expectation is therefore to find an alignments corresponding to exons. The alignments are ordered by quality, though you are provided with a **Sort by:** menu to alter the order to taste⁷.

Look at the first alignment for the best matching **PAX6** transcript. It is the alignment of the very last exon of a **RefSeq** transcript with the end of the gene you exported from **Ensembl**.

Notice the lower case string of 'a's. The case indicates that they were ignored (filtered) as a Low complexity region whilst megablast was looking for identically matching words that might suggest matching regions. By themselves, the 'a's are

٦ [Score			Expect	Identities	Gaps	Strand
€	9659 b	its(5230)	0.0	5237/5240(99%)	2/5240(0%)	Plus/Plus
∍							
a	Query	28433	CCACTTC-	TAGGACTC	ATTTCCCCTGGTGTGTCAGTTCCA	AGTTCAAGTTCCCGGAAG	GTG 28490
լ	Sbjct	1490	ccacttca	AACAGGACTC	ATTTCCCCTGGTGTGTCAGTTCC	AGTTCAAGTTCCCGGAAG	STG 1549
s	Query	28491	AACCTGAT		TACTGGCCAAGATTACAGTaaaaa		
У 1	Sbjct	1550	AACCTGAT				
١	Query	28551			TAATTCAGTCAGTGACTATGGGG		
}	Sbjct	1610	GAAAGGAA	LATATTGTGT	TAATTCAGTCAGTGACTATGGGGA	ACACAACAGTTGAGCTT	 CA 1669

not sufficient evidence that a biological match exists. Only because the surrounding sequence is compellingly similar, can it be assumed that such a match does exist. The 'a's are replaced (lower case to indicate they were filtered) when the final alignment is computed. If you look a little further down the same alignment, you will see several other runs of 'a's and 't's for which the same explanation applies.

To use a global approach would be to imply that you were only interested in database entries that matched your query sequence from end to end. Generally, this is not true. You would usually be interested in a database sequence that was similar over any significant region.

Why not try them? End up with the alignments for the top hit in **E value** order.

Now use a version of **blast** (called **blastx**) to compare your genomic sequence with a protein database. **blastx** will translate a DNA query sequence in all six reading frames and compare each translation with a protein sequence database. Thus, in a similar fashion to that employed by the **Ensembl** pipeline, protein coding regions of the genomic DNA can be identified. For clarity, we will use only the well annotated human proteins of the **SwissProt** section of **Uniprot**. First go to the home of **blast** at:

http://blast.ncbi.nlm.nih.gov/Blast.cgi

In the Basic BLAST section, select blastx. Use the Enter Query Sequence Browse (or Choose File) button to upload file pax6 genomic.fasta.

In the Choose Search Set section, set the Database to UniProtKB/Swiss-prot prot(swissprot). Specify the

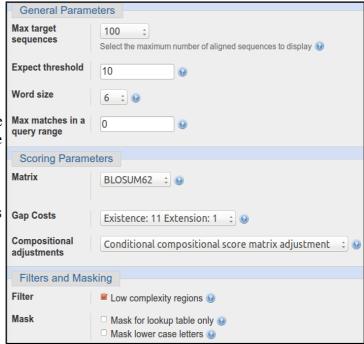

Organism as Human.

Take a look at the Algorithm parameters⁸.

The **Word size** choice is **2**, **3** or **6**. The default is **6**. We seek very close matches here, so the largest **Word size** would seem appropriate.

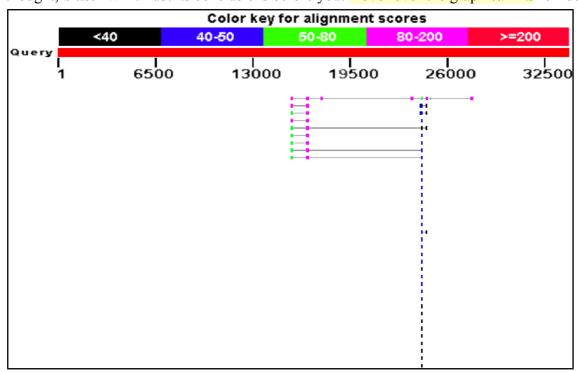

The default scoring matrix is **BLOSUM62**, but choices from both the **BLOSUM** and **PAM** families are offered.

Low complexity regions will be filtered by default.

Change nothing other than to ask blast to Show results in a new window. and click the BLAST button.

After minimal thought, **blastx** will thrust its conclusions before you. Hover over the graphical hits for identification.

What are the 9 stronger matches around base position 16,000?

Why would you expect exactly 9 matches around this point?

What do you make of the plethora of matches around **24,000**?

Here I will assume we have talked about these parameter and you are reasonably well informed of the issues

Move down to the textual list of the matches. Hopefully as you fully expected you will find the expected number of **Paired box** matches at the top of the list followed by many many **Homeobox** matches.

Why do you suppose the **Paired box** matches precede the **Homeobox** matches?

How do you suppose the **Max matches in a query range** parameter might be of value if this order was reversed? ___

Take a look at the alignments. You will see many places where regions have been filtered as non-informative. I suggest the one illustrated was filtered because it would match anywhere that was sufficiently **Serine** rich.

Score		Expect	Method	Identities	Positives	Gaps	Frame
81.3 bi	ts(199)	5e-29	Compositional matrix adjust	. 51/52(98%)	51/52(98%)	0/52(0%)	+3

PSI-BLAST

This program is used to find a comprehensive set of relatives of a protein. First, **BLAST** is used to find closely related proteins. From an alignment of these proteins a general "profile" (a Position Specific Scoring Matrix -**PSSM**) is computed. A **PSSM** is very similar in concept and purpose to an **HMM** profile in that it summarises significant features present in the sequences it represents.

A query against the protein database is then run using the **PSSM**, and a larger more widely associated group of proteins is found. This larger group is used to construct another **PSSM**, and the process is repeated until no more significantly matching new sequences can be detected, or the user tires of the whole process.

You have used PSI-BLAST integrated into Jpred already and similar ideas were used to create the PFAM alignments. Here we will use PSI-BLAST explicitly at the NCBI on the Paired DOMAIN of the PAX6 protein that you saved in a file earlier. It should be possible to detect a large family of PAX domains and to eventually multiply align them generating something like the Full alignment from the PFAM database viewed earlier.

Course Description/Notes

Move down to the **Alignments** section of the results and you will see that many of the top hits match the query exactly.

Note that many of the top hits come from the GenPept database (roughly equivalent to the TrEMBL section of UniProtKB).

How might the inclusion of relatively poor quality sequences and the presence of so much duplication have been minimised?

Move down far enough and you will see less perfect matches, some of which involve proteins with the extra 14 amino acids of isoform 5a of PAX6 HUMAN.

Having browsed your results sufficiently, click on the Go button to Run PSI-Blast iteration 2 It is at the bottom of the hit list.

After a few moments, PSI-**BLAST** will return with the results of searching through the database again using the PSSM derived from the hits of the first iteration(\square ed). This time the top of the list will be predominantly filled with hits that have already been incorporated into the PSI-**BLAST PSSM**. However, look far enough down the list and you will find some new highlighted yellow.

Once more, click on the button to **Run PSI-Blast iteration 3**. That is probably enough! It took 4 iterations before there were no more new sequences suggested for inclusion into the **PSMM** when I ran this last, so if you really want to take things to their logical conclusion, it should not detain you long.

Next, move to the top of the **Descriptions** list and **Select All**. Click on the **Multiple Alignment** button. You have elected to use the **NCBI** multiple alignment program **Cobalt** to align all the **PAX** domain sequences of your final **PSI-BLAST** iteration that match with an **Expect** score better than **0.001**. In an impressively short time, your alignment will appear.

Multiple Alignment Results - Pax-Domain P26367(4-130) (127 letters)

Move past the long list of proteins that have been aligned (the easiest way is to hide the **Descriptions** view).

At the top of the actual alignment, set View Format to Plain Text (.... and then hide the Descriptions again??), this being the easiest format to understand in a hurry. The alignment will have very ragged ends, but the important region of 120 or so amino acids representing the PAX domain is really quite impressive. In particular, the isoform 5a insertion is very convincing¹⁰.

Much more so than the **Full** alignment offered by **PFAM**, I would contend. Although, it has to be admitted, the **Pfam** alignment included more sequences and I suspect they would have gone for a less closely homologous set of sequences. Even so ... I think the alignment illustrated here is **MUCH** more beautiful!!

Model Answers to Questions in the Instructions Text.

Notes:

For the most part, these "**Model Answers**" just provide the reactions/solutions I hoped you would work out for yourselves. However, sometime I have tried to offer a bit moer back ground and material for thought? Occasionally, I have rambled off into some rather self indulgent investigations that even I would not want to try and justify as pertenent to the objective of these exercises. I like to keep these meanders, as they help and entertain me, but I wish to warn you to only take regard of them if you are feeling particularly strong and have time to burn. Certainly not a good idea to indulge here during a time constrained course event!

Where things have got extreme, I am going to make two versions of the answer. One starting:

Summary:

Which has the answer with only a reasonably digestible volume of deep thought. Read this one.

The other will start:

Full Answer:

Beware of entering here! I do not hold back. Nothing complicated, but it will be long and full of pedantry.

This makes the Model answers section very big. **BUT**, it is not intended for printing or for reading serially, so I submit, being long and wordy does not matter. Feel free to disagree.

From your investigations of Searching for sequence similarities in databases

When would **Mask lower case letters** be a useful thing to do?

Generally, whenever one might suspect the automatic masking algorithms of **blast** might miss a non informative region in a specific query sequence, obviously.

A specific example might be when a query sequence contained a significant informative region that was known to be common amongst the sequences being searched. If this region was left unmasked, **blast** would pick up so many similar matches to this one region that other interesting similarities might be obscured. By manually masking such a region by changing it to lower case, its matches would not be seen by **blast** and matches with other regions of the query sequence should be more apparent.

Which parameters would **blast** need to **automatically adjust** to cater for short input sequences (such as primers being tested for uniqueness), and why?

The **word size**: Clearly, if you are trying to find matches for a primer (for example) of around **20** base pairs, it would be pretty silly to use a **word size** of **28** (default for **megablast**). A **word** the same size as the primer would find only exact matches. A **word** of about **7** would allow a couple of mismatches and would probably be most generally appropriate.

The **expect score**: As good chance matches between between a short query sequence and a large database will be abundant, it would not be sensible to choose a demanding (i.e. small) **expect score** to represent the limit of significance. In particular, a primer sized query sequence of around **20** base pairs might easily exactly match more than **10** times (generally the default maximum expect score for a significant match) just by chance. After all, there are only **4** bases, a string of **20** is not that long and the databases can be huge! Typically **blast** chooses very high **expect score** cut off for short query sequences, effectively removing the **expect score** filter altogether.

Earlier versions of **blast** did not automatically adjust these parameters. When a short query sequences were selected, suitable adjustment was left to the user. Without sensible parameter adjustment, results could be greatly confusing. For example, a **21** base pair primer could easily match perfectly more than **10** times against a large DNA sequence database. **blast** is set to ignore matches that are expected to occur more than **10** times by chance. Thus even exact matches with such a small sequences would be ignored! Now automatic parameter adjustment is undertaken by **blast**, the user does not really have to think too hard. However, it does seem to be a good idea to know what **blast** is doing and why.

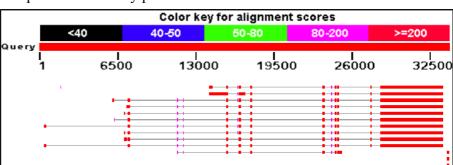

Why do you suppose that a few of the exons of the first 11 matches do not achieve the maximum score?

Summary:

Each local region of significant alignment between a database entry and a query sequence is scored independently. The scoring method that governs the alignment score colour in this graphic, reflects both the quality of the match and its length. Unless a particular region is of sufficient length, it cannot achieve the 200 bit threshold even if the alignment is perfect. Note that is is the shorter regions that fail to reach the status. All of the illustrated local alignments associated with PAX6 transcripts are essentially perfect.

Full Answer:

In common with most database searching programs, **blast** compares query sequences with database entries using a local strategy. The overall evaluation of a particular query sequence is taken to be the highest local score.

Individual local matches are coloured according to individual quality. In this query, all true matches should be perfect, or very nearly so. Scores might therefore be expected to be maximal (>=200). However, they are not? Some only manage a score in the range 80-200.

The score referenced for this purpose is the **bit score**. For a full, no holds barred definition of this score, try <u>here</u>. I prefer this somewhat gentler version:

"The **bit score** gives an indication of how good the alignment is; the higher the score, the better the alignment. In general terms, this score is calculated from a formula that takes into account the alignment of similar or identical residues, as well as any gaps introduced to align the sequences. A key element in this calculation is the "substitution matrix", which assigns a score for aligning any possible pair of residues. The **BLOSUM62** matrix is the default for most **BLAST** programs, the exceptions being **blastn** and **MegaBLAST** (programs that perform **nucleotide**—**nucleotide** comparisons and hence do not use protein-specific matrices). Bit scores are normalized, which means that the bit scores from different alignments can be compared, even if different scoring matrices have been used."

Still too scary? The important things to note are that:

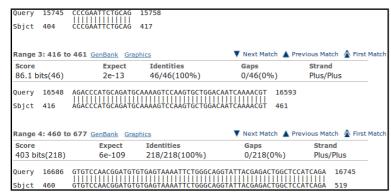

- These scores are based on a simple DNA scoring matrix (1 for a match, -2 for a mismatch by default for **megablast**), plus penalties for gaps. So scores will be limited by the length of the alignment, ignoring gaps.
- The scores reflect penalties for **indels** (**in**sertions or **del**etions).
- The scores are normalised so that they do not depend on the chosen scoring matrix. This allows bits scores from searches using different scoring matrices to be compared.

This being so, **bit scores** will reflect the length of an alignment as well as its quality. If an alignment is very short, it might be perfect but still not achieve a very high value. **bit scores** are designed to reflect significance, not just local quality. A short perfect match clearly can be less significant than a longer less perfect match. That is what you see illustrated here.

You can see evidence of what is occurring in the alignments further down your results. Here is illustrated one of the 80-200 exons that occur in all transcripts at position 24,346¹¹. The match is perfect, but the length of the exon is consistently just to short to get to the heady >=200 level.

Note how imperfectly **blast** finds exon/intron boundaries. If the start of an intron happens to match the start of the next exon, **blast** will included the bases in two alignments¹². It is not looking for exons and introns as was **spline**, it just mindlessly seeks matches.

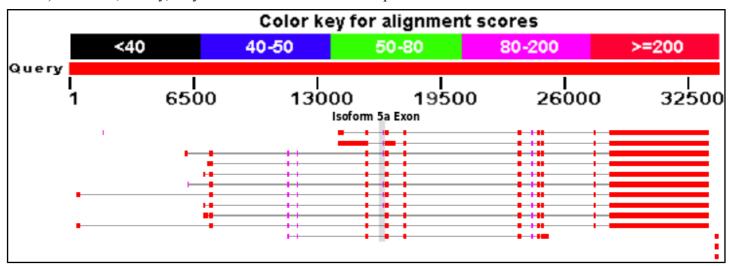

For a further example, look at the exon that is found only in the **isoform 5a** transcripts. It is tiny (42 base pairs) and scores well below even thought it is a perfect match.

Note that the alignment is **46** base pairs long due to **blast** adding on two bases either side that are actually the highly conserved intron start and end base pairs. As you can see, these extra base pairs occur in the preceding and succeeding alignment also.

Explain why one exon in the reasonably consistent region, does not appear in all of the transcript matches?

Well I refer to the **isoform 5a** exon, of course. The tiny inconsistent one about **9** exons in from the right (when it exists). This will, clearly, only occur in **isoform 5a** transcripts.

^{12 6} base pairs (Sbjct: 1081-1086, CAGGTA) occur in both the first two matches illustrated. Just 1 base pair is shared between the 2nd and 3rd match (Sbjct: 1234, G).

Which of the Refseq PAX6 transcripts corresponds to isoform 5a?

Summary:

As I am sure you are tired of noting by now, all the transcripts with the extra tiny exon around position 1,600 in the genomic sequence are **isoform 5a** transcripts. See the illustration for the previous answer.

Full Answer:

The **isoform 5a** transcripts can be spotted most easily from the graphic. They are the ones with the extra small exon slightly to the left of middle (around base position 1,600). For example, the **first**, **second** and **third blast** matches displayed. If you hover over all the full length matches with your mouse, you will see that they are **transcript variants 11**, 10, 8, 7, 6, 5, 4, 2, 1, 3 and 9 (in the vertical order of the graphic).

Stated with the unequalled poetry of **RefSeq Accession Code** and lyrical **Title** Line, the list of those with the extra exon becomes:

TITLE	ACCESSION CODE
Homo sapiens paired box 6 (PAX6), transcript variant 11, mRNA	NM_001310161.1
Homo sapiens paired box 6 (PAX6), transcript variant 10, mRNA	NM_001310160.1
Homo sapiens paired box 6 (PAX6), transcript variant 8, mRNA	NM_001310158.1
Homo sapiens paired box 6 (PAX6), transcript variant 5, mRNA	NM_001258463.1
Homo sapiens paired box 6 (PAX6), transcript variant 4, mRNA	NM_001258462.1
Homo sapiens paired box 6 (PAX6), transcript variant 2, mRNA	NM 001604.5

Yes well, that was fun? The message of the question was to ensure you could see how to spot the **isoform 5a** transcripts (again!), not to list them! But, never mind, doing so was in fine tune with the ennui of the moment.

Additional Meanderings:

That really should not detain anyone but me? They belong after the consideration of masking the run of As for the **megablast** you ran. I just enjoyed this detour, so I keep it somewhere low profile. The whole journey leads nowhere of any note, so, should you decide to read, expect little!

The **500** base pairs of 3' flanking sequence added on to the **Ensembl** sequence for "good measure", is not part of the alignment (as would be expected). This can be seen easily if you look at the end of the alignment illustrated above, which is the alignment of the last exon of a transcript.

The entire length of this transcript is 6,732 base pairs.

Homo sapiens paired box 6 (PAX6), transcript variant 11, mRNA Sequence ID: ref|NM_001310161.1| Length: 6732 Number of Matches: 11

The entire length of the genomic query sequence is **34,170** base pairs.

Query ID |c||Query_71179

Description pax6-genomic sequence

Molecule type nucleic acid

Query Length 34170

The alignment ends at position position 6,729 of the mRNA (3 from the end) and position 33,670 of the genomic Sbjct

```
Query 33601 ATTTGACATCCTGGCAAATCACTGTCATTGATTCAATTATTCTAATTCTGAATAAAAGCT 33660
Sbjct 6660 ATTTGACATCCTGGCAAATCACTGTCATTGATTCAATTATTCTAATTCTGAATAAAAAGCT 6719
Query 33661 GTATACAGTA 33670
Sbjct 6720 GTATACAGTA 6729
```

sequence (exactly 500 base pairs from the end).

The **3** missing base pairs of the mRNA are all **As**, due to **polyadenylation**. Position **6,729** being recorded as a **polyA** site by **RefSeq**. A very short **polyA** tail surely? But there is no telling what stage of the mRNA is recorded on **RefSeq**. **Wikipedia** says:

```
polyA site 2495
//gene="PAX6"
//gene_synonym="AN; AN2; D115812E; FVH1; MGDA; WAGR"

6541 aaaaaaatag aataagaaac ctgatttta gtactaatga aatagcgggt gacaaaatag 6601 ttgtctttt gatttgatc acaaaaaata aactggtagt gacaggatat gatggagaga 6661 tttgacatcc tggcaaatca ctgtcattga ttcaattatt ctaattctga ataaaagctg 6721 tatacagtaa aa
```

"The tail is shortened over time, and, when it is short enough, the mRNA is enzymatically degraded."

Of course, the neatness of this observation does reflect less some profund biological truth than it does that this mRNA just happens to be one that extends furthest to the right in the genome, and there is no chance match between the **polyA** tail and the extra **500** bases of genomic sequence you added on when extracting it from **Ensembl**.

The journey was fun even though the destination was dubious. Much the way of a considerable portion of life in general one might reflect?

What are the 9 stronger matches around base position 16,000?

Matches between the regions of genomic DNA encoding **Paired Box** domains.

Why would you expect exactly 9 matches around this point?

Because that is how many **Paired box** domains are suggested to be in the human genome by counting the number of quality **mRNA** sequences in **RefSeq** claiming to include a **Paired box** coding region. There is **PAX6** plus its **8** paralogues, imaginatively all named:

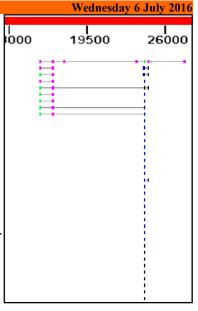

PAX1, PAX2, PAX3, PAX4, PAX5, PAX6, PAX7, PAX8 & PAX9

Model Answers
What do you make of the plethora of matches around **24,000**?

These are matches between human **mRNA** sequences with the regions of genomic DNA encoding **Homeo Box** domains. As you discovered from **Interpro**, there are many of these.

The thin line joining features implies that those features relate to the same database entry.

Notice that 4 of the 9 proteins matching a **Paired box** genomic region also match a **Homeo box** region. the remaining 5 do not. This implies that 4 of the 9 proteins corresponding to the hits detected here have a **Paired box** domain near the start of the protein and a **Homeo box** domain further along. This is exactly as was suggested by the **PROSITE** annotation you examined.

Why do you suppose the **Paired box** matches precede the **Homeobox** matches?

Because they score more highly and so, in the opinion of **blast**, are more worthy. Primarily, they score more highly because they are longer. The list is ranked by **E Value**. Good matches with long sequence are less likely to occur by chance than equally good matches with shorter sequences.

Possibly a more interesting question¹³ might have been: "Why are not all the hits which include both domains at the top of the list?". Surely they should be, as they match over a longer proportion of the query sequence and so must, in general at least, be of the greatest significance.

They do not always come at the top of the list because **blast** scores each matching region individually and uses the ranking scores associated with the single region with the highest **E Value** to evaluate the similarity of the entire database entry with the query. This has to be a dubious practice surely? But, it appears to work, so why complain.

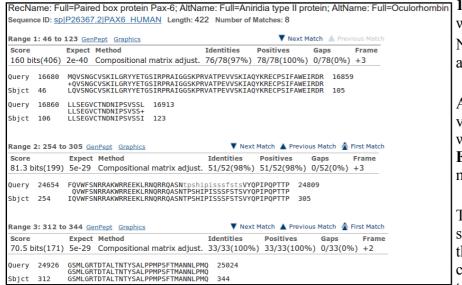

To justify this last assertion, Look at your top hit.

Description

Max score | Total score | Cover | Value | Ident | Accession |

RecName: Full=Paired box protein Pax-6; AltName: Full=Aniridia type II protein; AltName: Full=Oculorhombin | 160 | 767 | 3% | 2e-40 | 97% | P26367.2

E Val = 2e-40, Max score =

160, Total score 767 associated with the whole of P26367.2

Now look at the first few individual regional alignments for this hit.

As you can see, the E Value and Max score values used to evaluate the whole protein were computed from just the best (ranked by E Value) local alignment! Crude, but never mind

The **Total score** for the entire protein is the sum (rounded up to the nearest integer) of all the bit scores for all **8** local alignments computed for this protein (I suggest you just trust me on this assertion).

Wednesday 6 July 2016 **Model Answers**

How do you suppose the **Max matches in a query range** parameter might be of value if this order was reversed?

If Paired boxes had been more prolific, then the number of Paired box matches might have filled the blast hit list before the highest scoring **Homeo box** hit was registered.

If Homeo boxes were longer, and so justified a better E value, then the number of Homeo box matches might have filled the **blast** hit list before the highest scoring **Paired box** hit was registered.

Either of these situations would be very unfortunate, but easily avoided by setting the Max matches in a query range parameter to something sensible (50 say). This would ensure that only the top 50 items in the blast hit list would be dominated by the strongest hit.

For further discussion of the parameter, see above.

How does this "non-informative" region match expectations suggested by **Prosite** and the **Feature table** of **Uniprot** for **PAX6 HUMAN**?

discussed the prettiest one above. The region overy 24654 FOWFSNRRAKWRREEKLRNORROASN discussed is comprised largely of Serines, Prolines, Sbjct 254 Threonines & Isoleucines the 15 residues between 294-308.

blast identifies two non-informative regions. I only 81.3 bits(199) 5e-29 Compositional matrix adjust. 51/52(98%) 51/52(98%) 0/52(0%) +3

The second (to be found much further down your blast Alignments output) is comprised entirely of Arginines, Luccines and Lysines and Glutamines, the 10 residues between 203 - 212.

Score		Expect	Method	Identities	Positives	Gaps	Frame
85.9 b	its(211)	3e-16	Compositional matrix adjust.	56/66(85%)	58/66(87%)	5/66(7%)	+3
Query	23649		VPDGCQQQEGGGENTNSISSN VP DGC000EGGGENTNSISSN				13
Sbjct	162		VPGQPTQDGCQQQEGGGENTNSISSN				
Query	23814	IEALEK IEALEK	23831				
Sbjct	222	IEALEK	227				

Uniprotkb also suggests there are two compositionally biased regions.

Compositional bias	131 – 209	79	Gln/Gly-rich
Compositional bias	279 – 422	144	Pro/Ser/Thr-rich

Well, hardly an exact match, but there is approximate agreement? One would certainly suppose that blast is only willing to mask fairly severe cases of compositional bias. It is also probable that blast has a rather more mechanistic (i.e. non-biological) interpretation of what **computational bias** is?

PROSITE also predicts the more obvious region of **computational bias**, rather more generally:

"An octapeptide and/or a homeodomain can occur C-terminal to the paired domain, as well as a Pro-Ser-Thr-rich C-terminus"

PSI-Blast

What do you suppose the choice of **Pseudocount** might influence?

I clicked with confidences upon the link to the help. It opined as illustrated.

I suppose the next step is to read **PMID 19088134**? There is most certainly no elucidation amongst the strangle of words offered here?

The article **Abstract** says:

"Position specific score matrices (PSSMs) are derived from multiple sequence alignments to aid in the recognition of distant protein sequence relationships. The PSI-BLAST protein database search program derives the column scores of its PSSMs with the aid of pseudocounts, added to the observed amino acid counts in a multiple alignment column. In the absence of theory, the number of pseudocounts used has been a completely empirical parameter. This article argues that the minimum description length principle can motivate the choice of this parameter. Specifically, for realistic alignments, the principle supports the practice of using a number of pseudocounts essentially independent of alignment size. However, it also implies that more highly conserved columns should use fewer pseudocounts, increasing the inter-column contrast of the implied PSSMs. A new method for calculating pseudocounts that significantly improves PSI-BLAST's; retrieval accuracy is now employed by default."

The article itself, continues in like vein how about we close our eyes and accept the defaults? I would just wonder why the whole thing does not commence with, at least an attempt, to answer the question in the forefront of my inquiry, which is .. "WHAT, in the current context, IS a pseudocount?". I do not believe it is as tricky as they appear to wish us to believe. I will try again later, when my view of the world is less storm infested.
